

Patient ID : PA01

CT Scan of Thorax

Report:

Plain axial scans were taken in the region of interest. Intravenous contrast enhanced axial scans were taken from the thoracic inlet to the lung bases. Study reveals:

Trachea & bronchi: Trachea is normal in diameter, shape, position & bifurcation. No evidence of any narrowing or intraluminal mass lesion. Right and left main bronchi are normal in size & diameter.

Lungs & Pleura: Large right sided pneumothorax is seen with mild pleural effusion showing air fluid level with compression atelectasis of right lung. No pleural thickening is seen.

Minimal left pleural effusion is seen with consolidation posterior basal segment left lower lobe. No lung mass or nodule is seen.

Mediastinum: Heart & major mediastinal vessels are normal. No abnormal mediastinal lymphadenopathy is seen. No mass lesion is seen. No evidence of pericardial effusion. Moderate pneumomediastinum is seen with extension of air in visceral spaces of neck, bilateral chest wall and in right axilla.

Chest wall & axillae: Chest wall musculature is normal. Bony thorax is normal. Bilateral axillae are normal. No evidence of axillary lymphadenopathy.

Impression: Large right hydropneumothorax with small air fluid level causing compression atelectasis of right lung.

Minimal left pleural effusion with consolidation posterior basal segment left lower lobe.

Moderate pneumomediastinum with extension of air in visceral spaces of neck, bilateral chest wall and in right axilla.

Adv: Clinical Correlation
